## 1 Packages used

```
library(DataScienceExercises)
library(ggplot2)
```

## 2 Developing a ggplot - the general workflow

Make a shortcut to the data and inspect it:

```
gdp_data <- DataScienceExercises::gdplifexp2007
head(gdp_data, 3)
```

```
##      country continent lifeExp      pop gdpPercap
## 1      China      Asia  72.961 1318683096  4959.115
## 2      India      Asia  64.698 1110396331  2452.210
## 3 United States Americas 78.242  301139947 42951.653
```

Plots in ggplot2 are created layer by layer. We now go through each step that, in the end, will produce the following plot:

Note: size of bubbles represents population. Data: Gapminder

We start by creating the basic `ggplot2` object, which is best thought of as a fancy list. To this end we use the function `ggplot2::ggplot()`

```
gdp_plot <- ggplot2::ggplot()
typeof(gdp_plot)
```

```
## [1] "list"
```

When we call this list, the plot described by it gets rendered:

```
gdp_plot
```

Of, course, there is no plot since the list is basically empty. All the specifications in the `ggplot2::ggplot()` function are best thought of as default values. In our case we first specify the data set we use for our plot:

```
gdp_plot <- ggplot2::ggplot(  
  data = gdp_data  
)
```

But this alone does not do anything good. We also need to inform `ggplot2` on how it should map the variables from the data set onto the plot. In a first step, let's clarify that the variable `gdpPercap` should be mapped on the x-axis and the variable `lifeExp` on the y-axis.

This is done via the argument `mapping` and the function `ggplot2::aes()`, which takes as arguments the aesthetics of the plot and the variable names that should be plotted on them:

```
gdp_plot <- ggplot2::ggplot(  
  data = gdp_data,  
  mapping = ggplot2::aes(  
    x = gdpPercap,  
    y = lifeExp  
  )  
)  
gdp_plot
```

This looks better. Note that `ggplot2` chooses a default range for the axes based on the range of the variables in the underlying data set:

```
min(gdp_data$lifeExp); max(gdp_data$lifeExp)
```

```
## [1] 39.613
```

```
## [1] 82.603
```

```
min(gdp_data$gdpPerCap); max(gdp_data$gdpPerCap)
```

```
## [1] 277.5519
```

```
## [1] 49357.19
```

We now want to add an additional layer with data points on our plot. Points are so called `geom`: a certain geometrical object representing data points. The function to add points is called `ggplot2::geom_point()` and we literally just add it to our plot:

```
gdp_plot <- gdp_plot + geom_point()  
gdp_plot
```

This already reveals much of the general workflow involved in creating a plot: define a raw object and add and refine layers. Looking at the plot above, one thing that is missing is that the dots are filled in different colors, representing the continents of the countries, and the size of the dots represent the population size of the countries.

To achieve this we need to map the variable `continent` from the data set to the aesthetic color in the plot, and the variable `pop` to the aesthetic `size`:

```
gdp_plot <- ggplot2::ggplot(  
  data = gdp_data,  
  mapping = ggplot2::aes(  
    x = gdpPercap,  
    y = lifeExp,  
    size = pop,  
    color = continent  
  )  
) +  
  ggplot2::geom_point()  
gdp_plot
```

What is not so nice is that the points are partly overlapping and bigger points might conceal smaller points below them. To address this problem we might make the plots a bit transparent. Since this is not a mapping from a variable from the data set to an aesthetic, but a general setting that should apply to all points equally, we do not specify it via the argument `aes`, but via the parameter responsible for transparency directly. This parameter is called `alpha` and we can set it for the affected geom directly:

```
gdp_plot <- ggplot2::ggplot(
  data = gdp_data,
  mapping = ggplot2::aes(
    x = gdpPercap,
    y = lifeExp,
    size = pop,
    color = continent
  )
) +
  ggplot2::geom_point(alpha=0.5)
gdp_plot
```

But now there is the danger for points to ‘melt into each other’. Better have their circle in black, and only color their interior. We can do so by replacing `color` in the aesthetics with `fill`, and set the color explicitly to `'black'`. However, this distinction between circle color and fill color is not available for all kind of point shapes. You need to search the internet for a shape that supports this distinction. If you looked, for instance, here you found that they shape with index 21 allows this:

```
gdp_plot <- ggplot2::ggplot(
  data = gdp_data,
  mapping = ggplot2::aes(
    x = gdpPercap,
    y = lifeExp,
    size = pop,
    fill = continent
  )
) +
  ggplot2::geom_point(
    shape=21, color="black", alpha=0.5
  )
gdp_plot
```

Progress cannot be denied! Now let's fix the labels and annotations of the plot. Here, the function `ggplot2::labs()` comes in handy. It accepts arguments such as `title`, `subtitle`, `caption`, and several more. The `help()` function gives further information about the possibilities.

In our case we want to add a `title`, specify the `x` and `y` axis, and add a `caption`:

```
gdp_plot <- gdp_plot +  
  ggplot2::labs(  
    title = "Life expectancy and income per capita",  
    caption = "Note: size of bubbles represents population. Data: Gapminder",  
    x = "GDP per capita (int. Dollar)",  
    y = "Life expectancy in years"  
  )  
gdp_plot
```

So far, so good. The x-axis is a bit clumsy, though. It would be better to scale the number down so that it shows 1000 dollars. The scale properties of the axes can be defined by the functions `scale_*_**()`, where the first `*` should be replaced by the aesthetic we want to adjust, and the second by a keyword indicating whether the variable is discrete or continuous, or whether we want to provide fully manual specifications. In our case we are interested in changing the x-axis, which represents a continuous variable (years). Thus we call `scale_x_continuous()`. Since we want to change the labels on the axis we specify the argument `labels`. To scale the labels we make use of a function from the `scales`-package: `scales::number_format()`. And to make this clear on the axis we add the suffix 'k':

```
gdp_plot <- gdp_plot +
  ggplot2::scale_x_continuous(
    labels = scales::number_format(scale = 0.001, suffix = "k")
  )
gdp_plot
```

Now let's turn to the legends. First of all we want to remove the legend for the bubble size since, first, the mapping of the bubble size is not straightforward to understand and, second, we already indicated that the bubble size represents population in the caption of the plot. There are several ways to do this: either we use the `scale_*_*()` function we already encountered with the argument `guide="none"`:

```
gdp_plot + ggplot2::scale_size_continuous(guide = "none")
```

Or we use a function that allows us to specify all kinds of legend properties: `ggplot2::guides()`. Here we take the aesthetic name as an argument and set it to `"none"`:

```
gdp_plot <- gdp_plot + ggplot2::guides(size = "none")
gdp_plot
```

The advantage of using `ggplot2::scale_size_continuous()` would be that we could stretch the limits a bit to make the differences more straightforward to see:

```
gdp_plot <- gdp_plot +
  ggplot2::scale_size_continuous(
    guide = "none",
    range = c(0.1, 24)
  )
```

Now we want to put the remaining legend to the bottom of the plot. Again, there are several ways to achieve this, but for such specific changes the function `ggplot2::theme()` is usually a good option. It allows us to change almost everything on a plot. The argument to place legends at the bottom is `legend.position` and already hints at the internal logic of `theme()`, which you might explore through the `help()` function yourself:

```
gdp_plot <- gdp_plot +
  ggplot2::theme(legend.position = "bottom")
gdp_plot
```

Note: size of bubbles represents population. Data: Gapminder

Since the `theme()` function is so extensive there are also many pre-defined themes for plots, which are best explored in the internet. A good default one is the black-and-white theme, which we can use via `ggplot2::theme_bw()`:

```
gdp_plot <- gdp_plot +  
  ggplot2::theme_bw()  
gdp_plot
```

Oups, while everythin looks nicer, some of our previous changes, such as moving the legend to the bottom and removing its title were overwritten! It, thus, makes always sense to first call the default theme, and *then* make further changes via `ggplot2::theme()`.

Of course, we can then also make further adjustments to the theme, e.g. by removing the panel of the plot. Removing elements of the plot via `ggplot2::theme()` requires us to set these elements via the function `ggplot2::element_blank()`:

```
gdp_plot <- gdp_plot +  
  ggplot2::theme_bw() +  
  theme(  
    legend.position = "bottom",  
    panel.border = ggplot2::element_blank()  
  )  
gdp_plot
```

Note: size of bubbles represents population. Data: Gapminder

Hm, but it would indeed be a bit nice to keep the axis lines of the x- and y-axis. Lets do this by specifying them explicitly via `ggplot2::element_line()`, which again allows for endless specification details:

```
gdp_plot <- gdp_plot +
  ggplot2::theme(
    axis.line = ggplot2::element_line(colour = "grey")
  )
gdp_plot
```

Note: size of bubbles represents population. Data: Gapminder

Its time to get picky! The ticks of the values should have the same color as the axis lines!!!

```
gdp_plot <- gdp_plot +  
  ggplot2::theme(  
    axis.ticks = ggplot2::element_line(colour = "grey")  
  )  
gdp_plot
```

Note: size of bubbles represents population. Data: Gapminder

Okay, you should get the general idea. What is more worrisome, to be honest, is the ugly title of the legend. Away with it!

```
gdp_plot <- gdp_plot +  
  ggplot2::theme(legend.title = ggplot2::element_blank())  
gdp_plot
```

Note: size of bubbles represents population. Data: Gapminder

So, the only thing that distinguishes our plot from the initial example is the color palette. There are many different palettes available, you can search for your favorite one in the internet. Here we use one provided by the package `RColorBrewer`, which can be used for the `fill-aesthetic` directly:

```
gdp_plot <- gdp_plot +  
  ggplot2::scale_fill_brewer(palette = "Dark2")  
gdp_plot
```

Note: size of bubbles represents population. Data: Gapminder

Thats it! This was, of course, only a tiny glimpse on what you can achieve using `ggplot2`, but it should suffice for the start. Moreover, what is more important, you learned about the general workflow when developing a plot: start with creating a list with `'ggplot2::ggplot()'` and then adjust your plot layer by layer until you are satisfied.

Here is the whole code we used for the figure:

```
gdp_plot <- ggplot2::ggplot(
  data = gdp_data,
  mapping = ggplot2::aes(
    x = gdpPercap,
    y = lifeExp,
    size = pop,
    fill = continent
  )
) +
  ggplot2::geom_point(
    shape=21, color="black", alpha=0.5
  ) +
  ggplot2::labs(
    title = "Life expectancy and income per capita",
    caption = "Note: size of bubbles represents population. Data: Gapminder",
    x = "GDP per capita (int. Dollar)",
    y = "Life expectancy in years"
  ) +
  ggplot2::scale_x_continuous(
    labels = scales::number_format(scale = 0.001, suffix = "k")
  ) +
```

```
ggplot2::scale_size_continuous(  
  guide = "none",  
  range = c(0.1, 24)  
) +  
ggplot2::scale_fill_brewer(  
  palette = "Dark2"  
) +  
ggplot2::theme_bw() +  
ggplot2::theme(  
  legend.position = "bottom",  
  legend.title = ggplot2::element_blank(),  
  panel.border = ggplot2::element_blank(),  
  axis.line = ggplot2::element_line(colour = "grey"),  
  axis.ticks = ggplot2::element_line(colour = "grey")  
)
```

Of course, for simple exploratory analysis, you do not need so many details as we just did, but for publication purposes its good to know how far you can get!

Another great thing is that the syntax remains largely the same, no matter whether you want to make a scatter plot as above, or a line graph or a histogram. All that changes is the particular `geom_*()` function used.

### 3 An alternativ line plot

To illustrate the similarities of the code used for a different plot type, we will now use a data set that is very similar to the one used previously, only this time we have observations for GDP per capita and life expectancy for several years, aggregated for the different continents. The data set is gain made available via the package `DataScienceExercises`:

```
gdp_data_agg <- DataScienceExercises::aggGDPlifexp
```

Again, we first inspect the data to get a feeling about the variables that are present:

```
head(gdp_data_agg, 3)
```

```
## # A tibble: 3 x 5  
##   continent year lifeExp      pop gdpPercap  
##   <fct>      <int> <dbl>    <dbl>    <dbl>  
## 1 Africa    1952   39.1 4570010.    1253.  
## 2 Africa    1957   41.3 5093033.    1385.  
## 3 Africa    1962   43.3 5702247.    1598.
```

Lets plot the dynamics of GDP per capita over time for the different continents. We can now simply copy-paste a lot of the code we have used before. Lets start with the uncontroversial beginning and just replace the name of the data set and the variable names:

```
gdp_dyn_plot <- ggplot2::ggplot(  
  data = gdp_data_agg, # <- Replaced  
  mapping = ggplot2::aes(  
    x = year, # <- Replaced  
    y = gdpPercap, # <- Replaced  
    color = continent#,  
    #fill = continent # <- Not necessary  
  )  
) +  
  ggplot2::geom_point()  
gdp_dyn_plot
```

This is not so bad! But it would be nice to add an additional geom that connects the dots with lines. No problem, simply add `ggplot2::geom_line()` to the plot:

```
gdp_dyn_plot <- gdp_dyn_plot +  
  geom_line()  
gdp_dyn_plot
```

Much of the code above only requires slight adjustments: the scaling of the x-axis should now be applied to the y-axis so we change `ggplot2::scale_x_continuous()` into `ggplot2::scale_y_continuous()`. Moreover, colors should change not for the fill but the color aesthetic, so `ggplot2::scale_fill_brewer()` becomes `ggplot2::scale_color_brewer()`:

```
gdp_dyn_plot <- gdp_dyn_plot +
  ggplot2::scale_y_continuous(
    labels = scales::number_format(scale = 0.001, suffix = "k")
  ) +
  ggplot2::scale_color_brewer(
    palette = "Dark2"
  )
gdp_dyn_plot
```

Aside from this, we can pretty much re-use almost the entire code from above with which we adjusted the legend, the labels, as well as the overall theme, only we can be so bold to remove the title of the x-axis via `axis.title.x = ggplot2::element_blank()`. Moreover, since we do not map the population size, `ggplot2::scale_size_continuous()` can now be removed, resulting in:

```
gdp_dyn_plot <- gdp_dyn_plot +
  labs(
    title = "The divergence of income per capita",
    caption = "Note: country data averaged over continents. Data: Gapminder",
    y = "GDP per capita (int. Dollar)"
  ) +
  ggplot2::theme_bw() +
  theme(
    legend.position = "bottom",
    legend.title = ggplot2::element_blank(),
    panel.border = ggplot2::element_blank(),
    axis.line = ggplot2::element_line(colour = "grey"),
    axis.ticks = ggplot2::element_line(colour = "grey"),
    axis.title.x = ggplot2::element_blank()
  )
gdp_dyn_plot
```

Note: country data averaged over continents. Data: Gapminder

Again, a very nice plot - and much faster to complete than the first one, thanks to the amazingly consistent syntax of `ggplot2`!)

## 4 Saving your plot

You can save your plot using the function `ggplot2::ggsave()`. The function saves, by default, the last plot you created, but it is better to specify the plot you want to save directly. Other important arguments are the file name (which also determines the format), and the size:

```
ggplot2::ggsave(  
  plot = gdp_plot,  
  filename = "gdp_plot.pdf",  
  width = 6, height = 4.2)
```
